# Outline

1. Starting point...
2. Do we have ways forward?
3. Added value of MFAs for exposure assessment

# Starting point

13 <b>Al</b> Aluminium	29 <b>Cu</b> Copper	28 <b>Ni</b> Nickel	82 <b>Pb</b> Lead	30 <b>Zn</b> Zinc	79 <b>Au</b> Gold	47 <b>Ag</b> Silver	78 <b>Pt</b> Platinum	51 <b>Sb</b> Antimony	4 <b>Be</b> Beryllium	14 <b>Si</b> Silicon	27 <b>Co</b> Cobalt	42 <b>Mo</b> Molybdenum	23 <b>V</b> Vanadium	50 <b>Sn</b> Tin	46 <b>Pd</b> Palladium	44 <b>Ru</b> Ruthenium	33 <b>As</b> Arsenic	76 <b>Os</b> Osmium	77 <b>Ir</b> Iridium	74 <b>W</b> Tungsten	73 <b>Ta</b> Tantalum	32 <b>Ge</b> Germanium	34 <b>Se</b> Selenium	31 <b>Ga</b> Gallium	48 <b>Cd</b> Cadmium	12 <b>Mg</b> Magnesium
------------------------------	---------------------------	---------------------------	-------------------------	-------------------------	-------------------------	---------------------------	-----------------------------	-----------------------------	-----------------------------	----------------------------	---------------------------	-------------------------------	----------------------------	------------------------	------------------------------	------------------------------	----------------------------	---------------------------	----------------------------	----------------------------	-----------------------------	------------------------------	-----------------------------	----------------------------	----------------------------	------------------------------

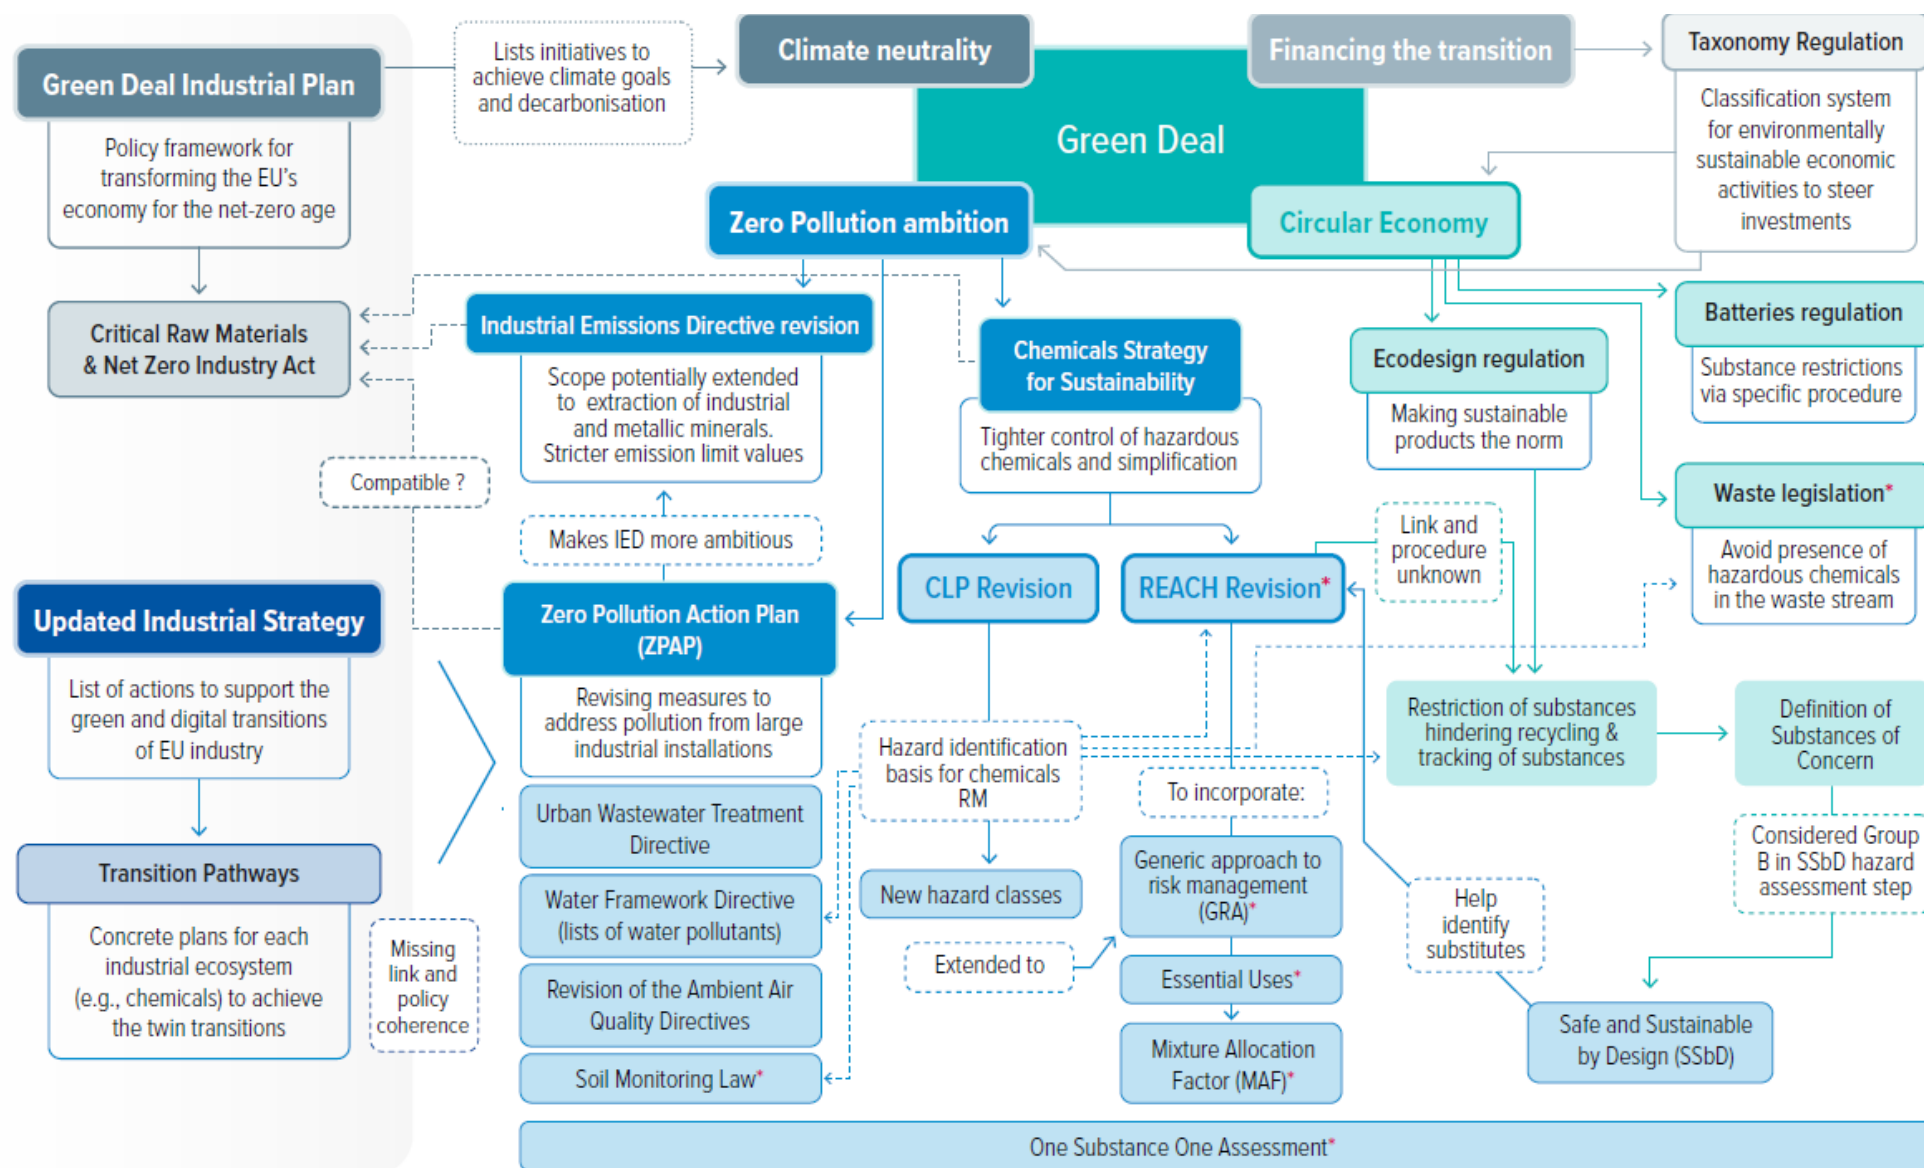

# Risk assessment/management

- Starting from the equation...

$$(Risk = hazard \times exposure)$$

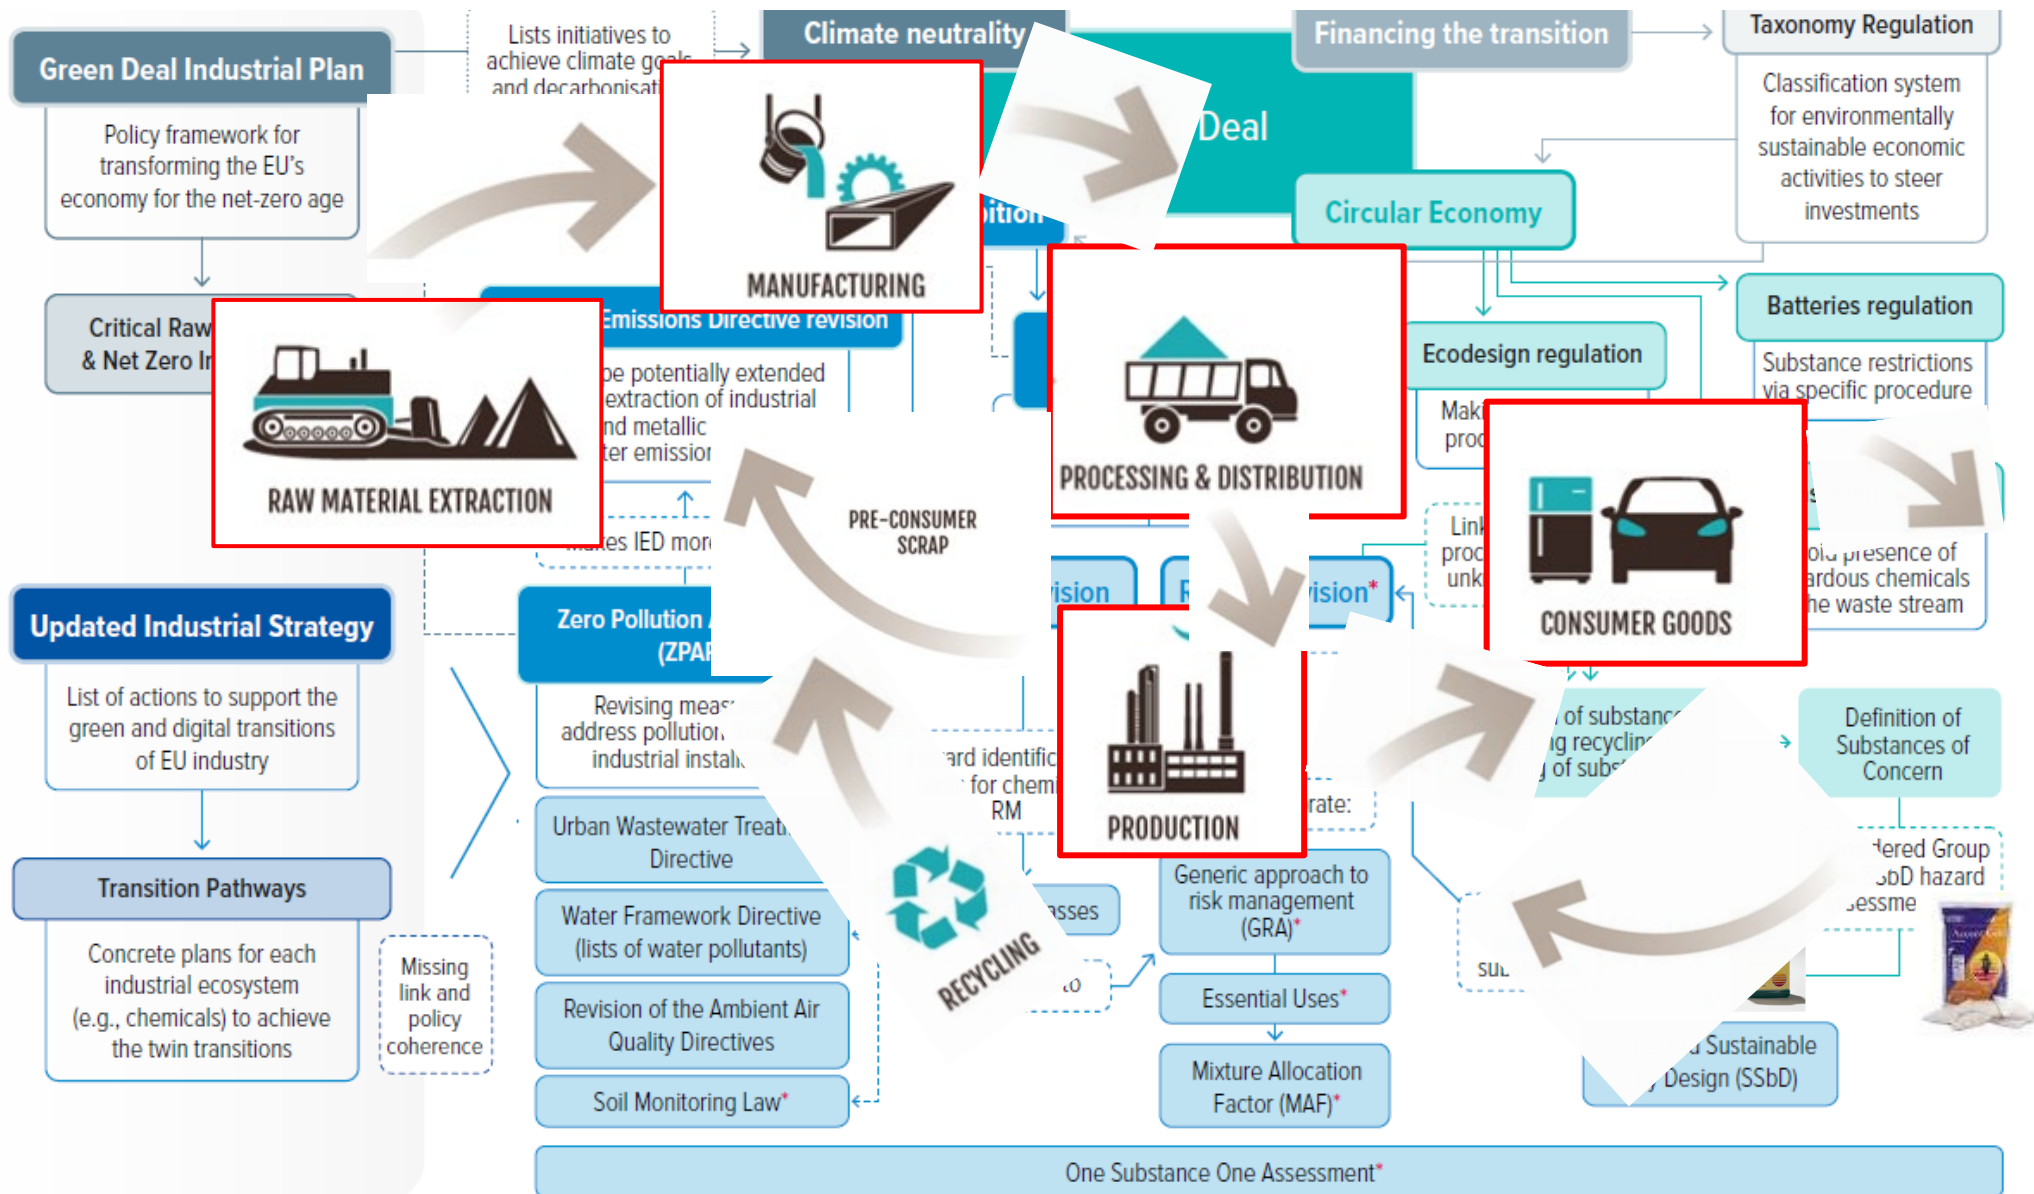

- By definition: **effective** risk management involves **identifying and evaluating chemical risks**, implementing appropriate measures to **control exposure**, and monitoring and reviewing the **effectiveness** of these actions
  - Conditions: good knowledge on hazard, **uses** and **exposure pattern**

# Risk management in practice (1): who and how?

# Risk management in practice (2): by substance (fate)

# Risk management in practice (3): challenges and results

$$(\text{Risk}^y = \text{hazard}^w \times \text{exposure}^x)^z$$

with w: number of substances, number of hazards

with x: unknown exposures

with y: perceptions of risks

with z: ways to regulate risks

**Uncertainty**

Tempting to focus on  
**hazard** of the **substance**,  
**more certain**

**Most efficient** risk  
management?

Can we refine this with  
data?

# Possible ways forward and tools

# Gathering of exposure information as part of REACH risk assessments (1)

- Sound use description entails
    - only relevant descriptors
    - grouping and splitting of ES considering similarity of exposure settings (not only economic aspects)
  - Hazard assessment defines the scope of the exposure assessment
    - structured approach under REACH
      - Hazard conclusion for each type of effect, exposure duration and exposure route
      - Risk characterisation (and thus exposure assessment) required for each hazard
- hazard potential sets the required level of information
- feedback loop: relevant exposure route (hazard vs. exposure potential)
- leading to more awareness for dermal exposure (for systemic effects)

# Gathering of exposure information as part of REACH risk assessments (2)

- Standard risk assessment under REACH
  - to cover the entire life cycle of the substance
  - to be described by “use descriptors”
  - top-down approach: (safe) conditions of use to be communicated down the supply chain
  - downstream users to comply or to communicate deviations from exposure scenario
- More collaborative approach possible
  - downstream user survey to obtain knowledge about
    - Conditions of use (processes/tasks, RMMs, exposure data?)
    - Substances handled in parallel (same metal compound) and associated tonnages
  - asking for information rather than imposing conditions of use via ES

# Gathering of exposure information as part of REACH risk assessments (3)

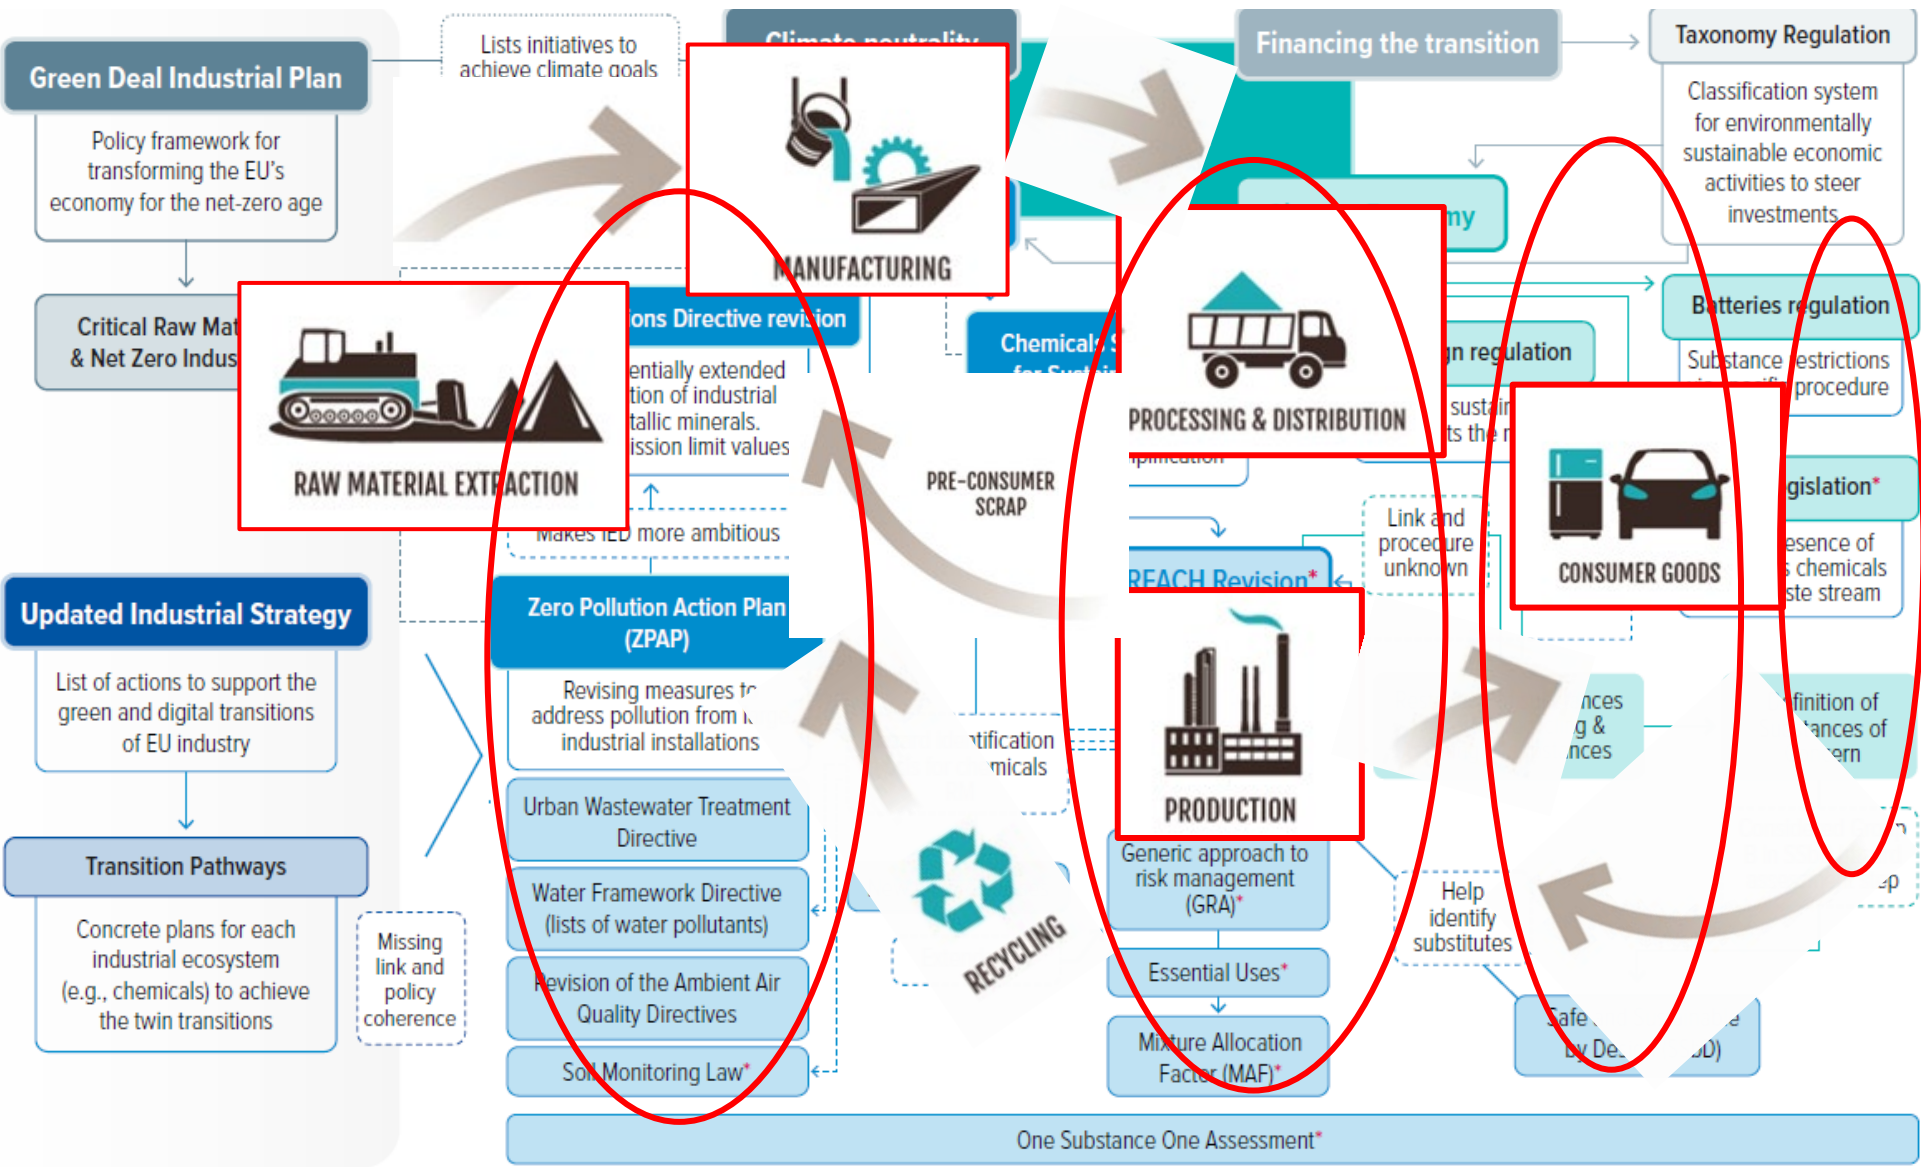

- Pros

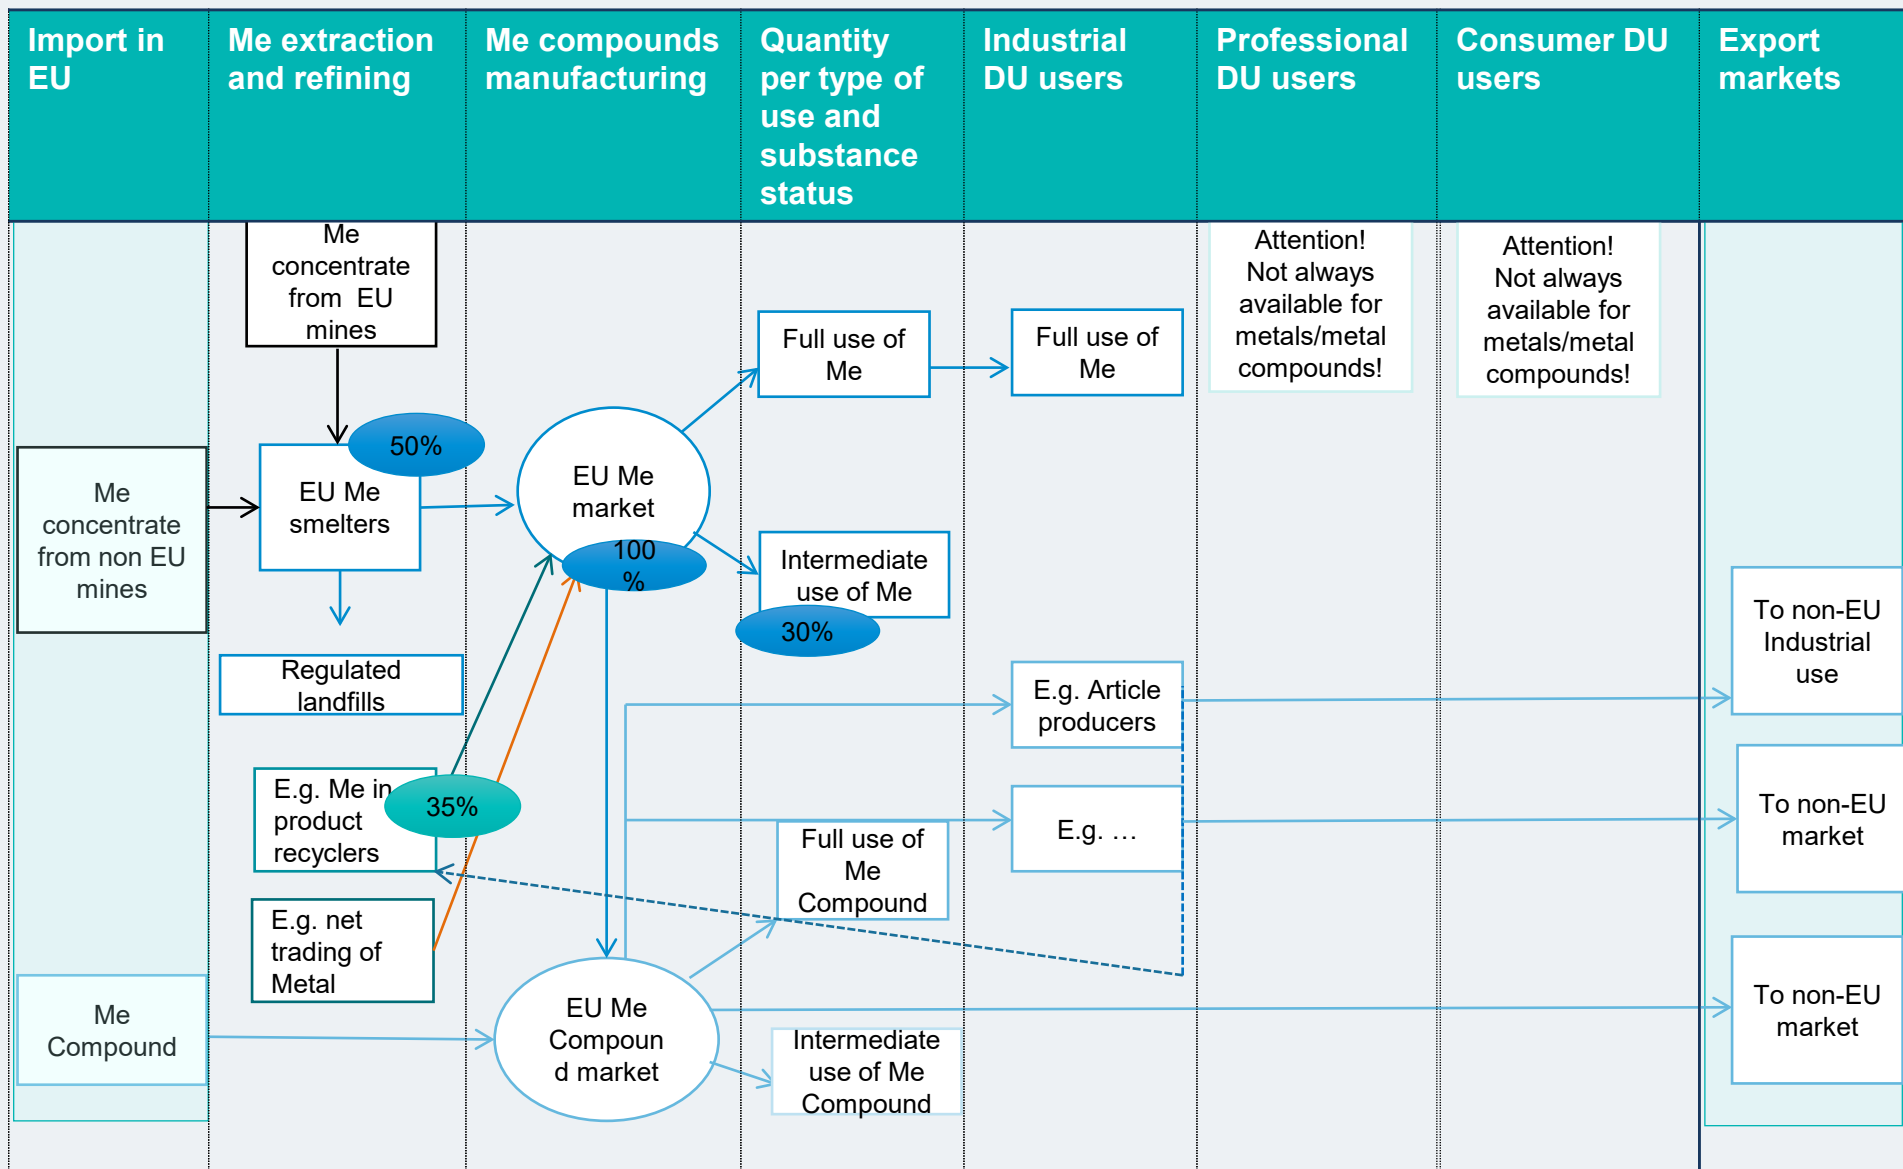

- structured approach
- extensive guidance available
- needs to be done anyway
- facilitates communication, discussion and understanding

- Cons

- registration is/was already expensive → additional costs for surveys
- regular updates required (as for any other exposure assessment...?)
- confidential information requires trustee
- compromise between specificity and generalisation (company-specific vs. sector-wide)

# Materials flow to avoid silo-working

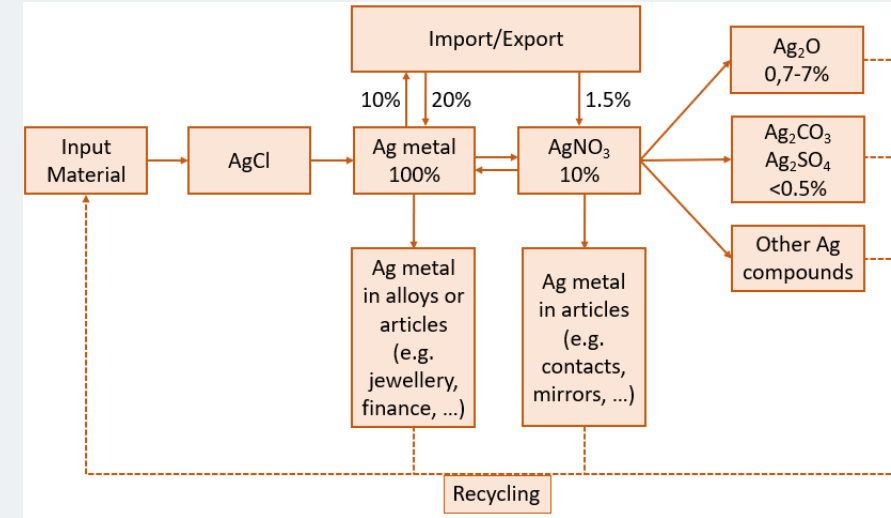

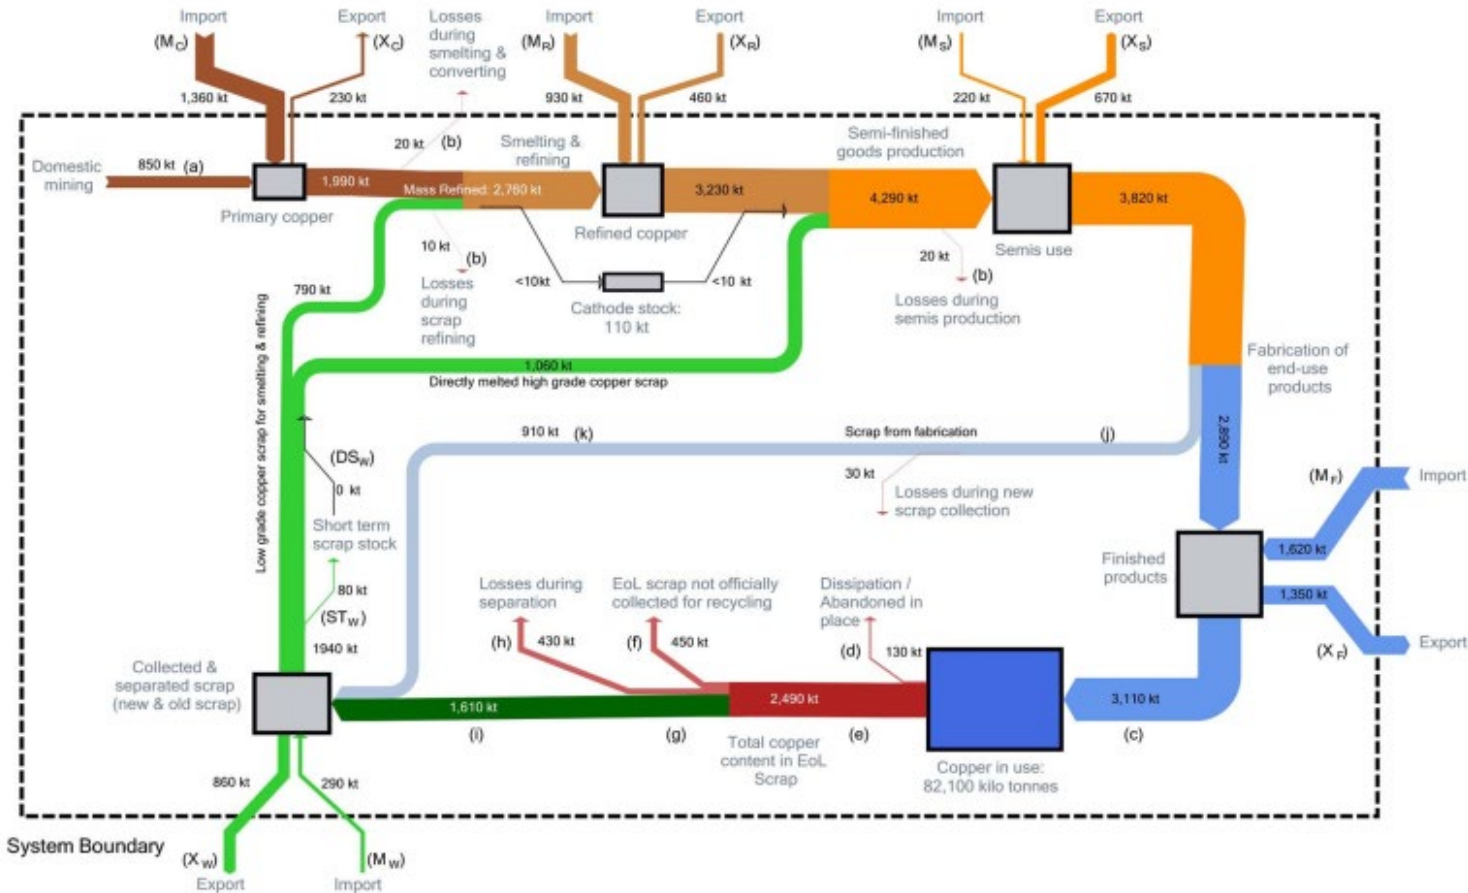

# Materials flow

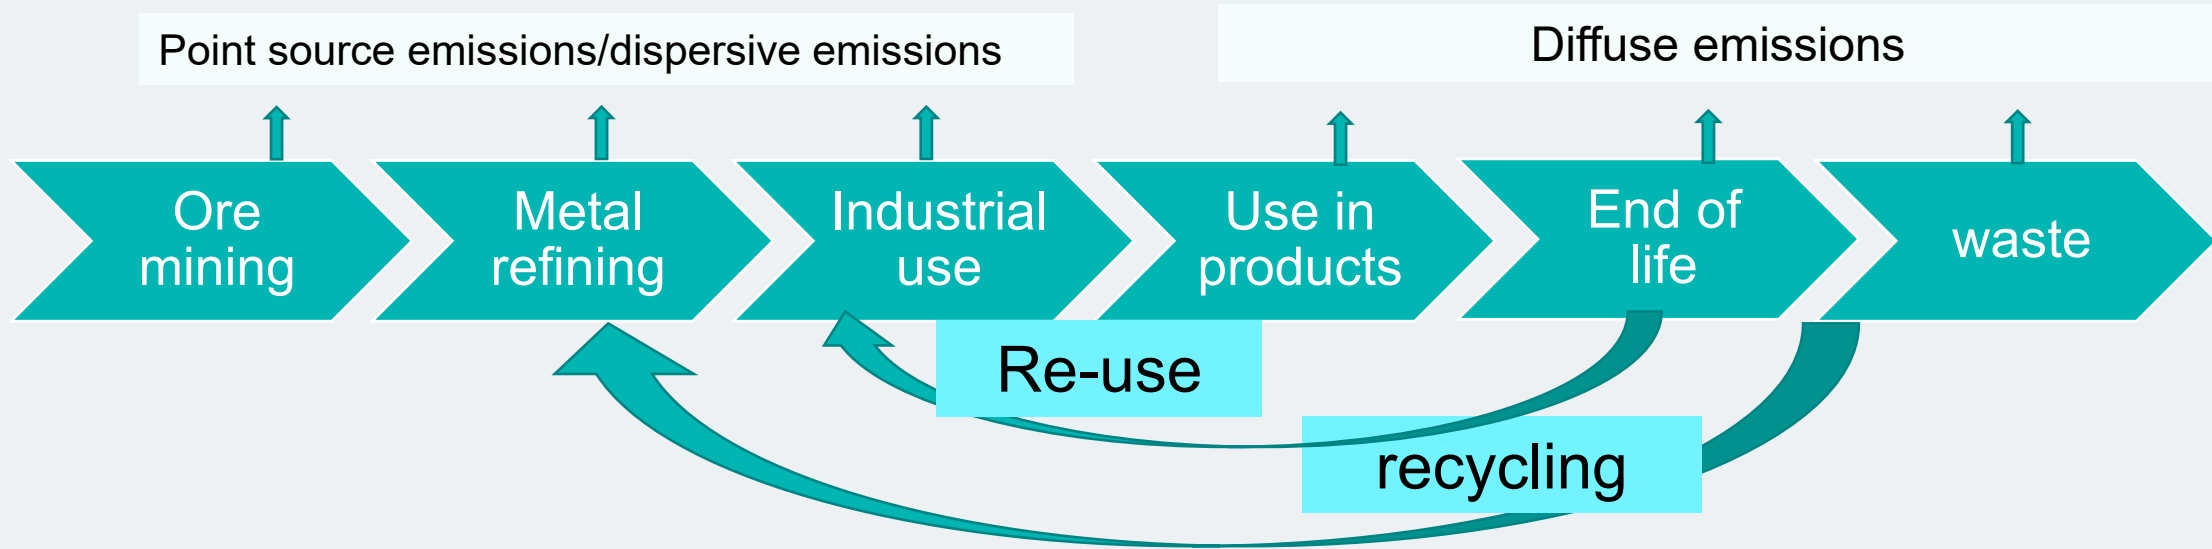

- Sequence of processes ranging from the extraction of raw material via its processing, reprocessing and machining up to the finished product, delivery to the end consumer, and recycling (different visuals)

# Where can it help?

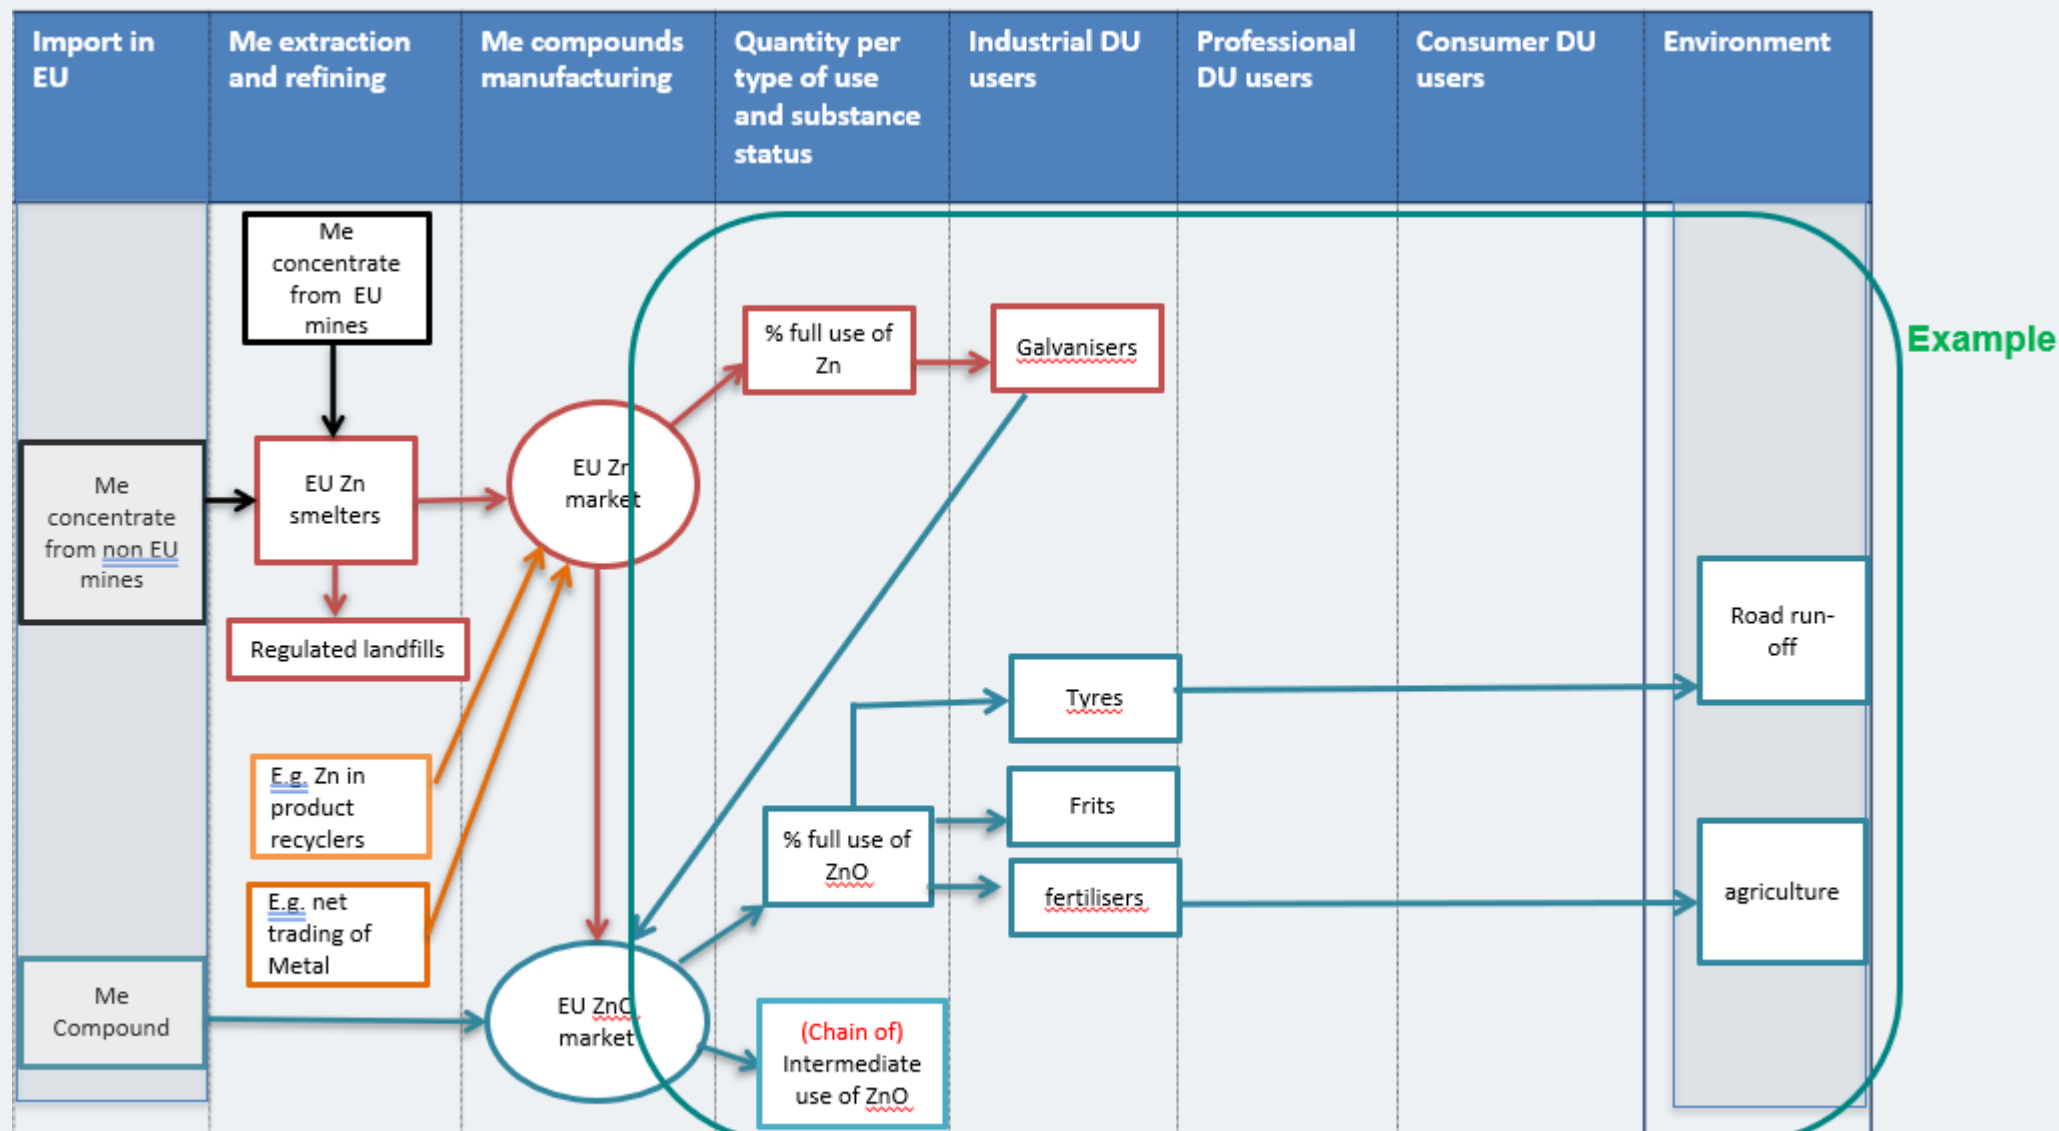

- Identifying 'wider picture'
- Identifying where:
  - exposures/releases may take place,
  - Material leakages take place (single use)
- Prioritisation of information required
- Prioritisation of risk management based on *exposure and materials leakage*
- Mainly qualitative

# Environmental emissions identified in the materials flow

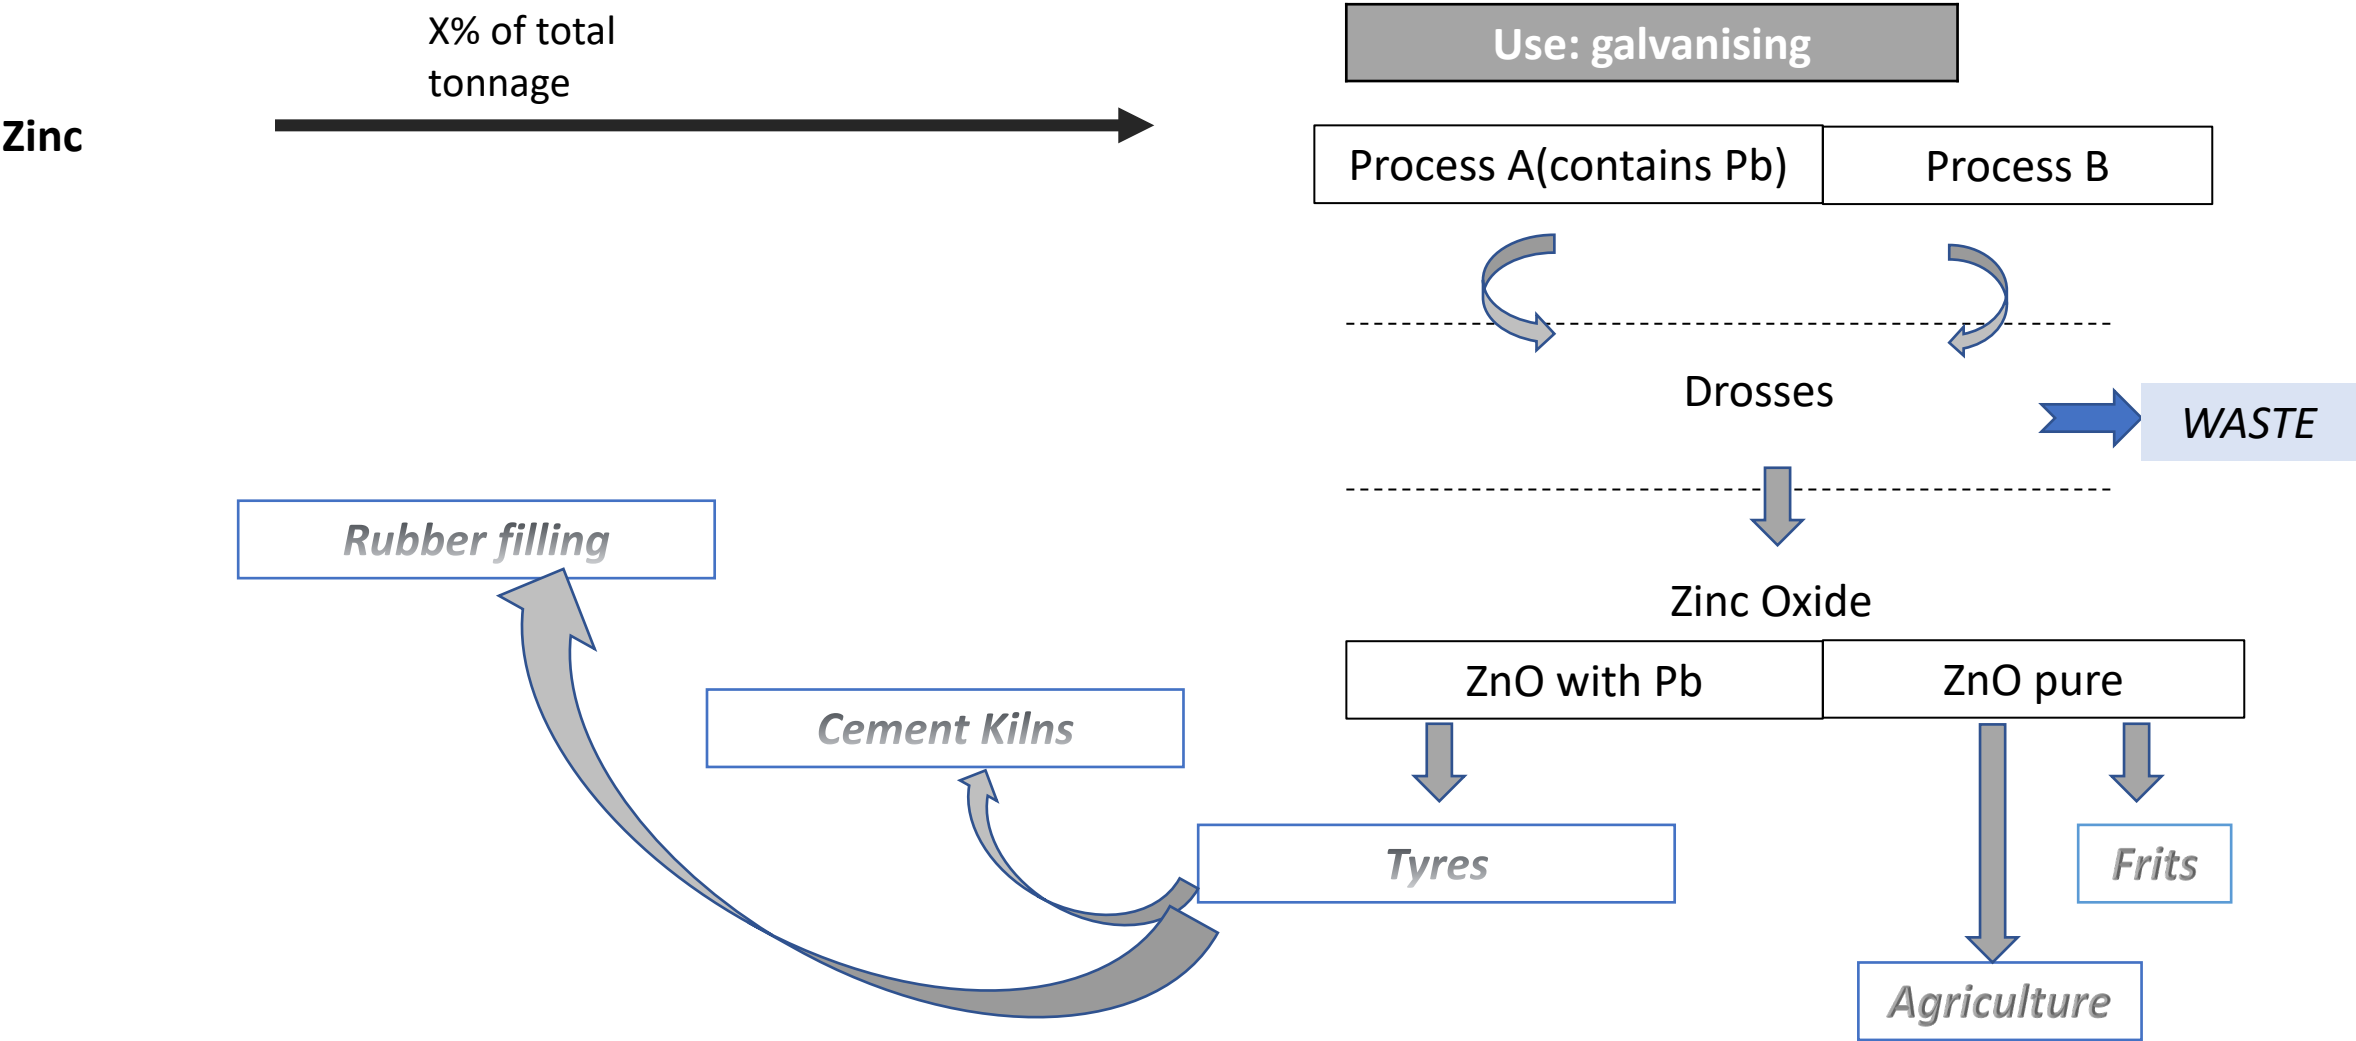

- Metal emissions can occur at all stages of the life cycle, as quantified in the materials flow
- Use of the metal in different products exposed to environment can result in diffuse emissions
- In general, point source-related industrial emissions are strictly regulated and controlled. This has resulted in a progressive and general reduction of industrial emissions over the past decades (see emissions of cadmium as an example)
- recycling and re-use prevents emissions from waste

# Example

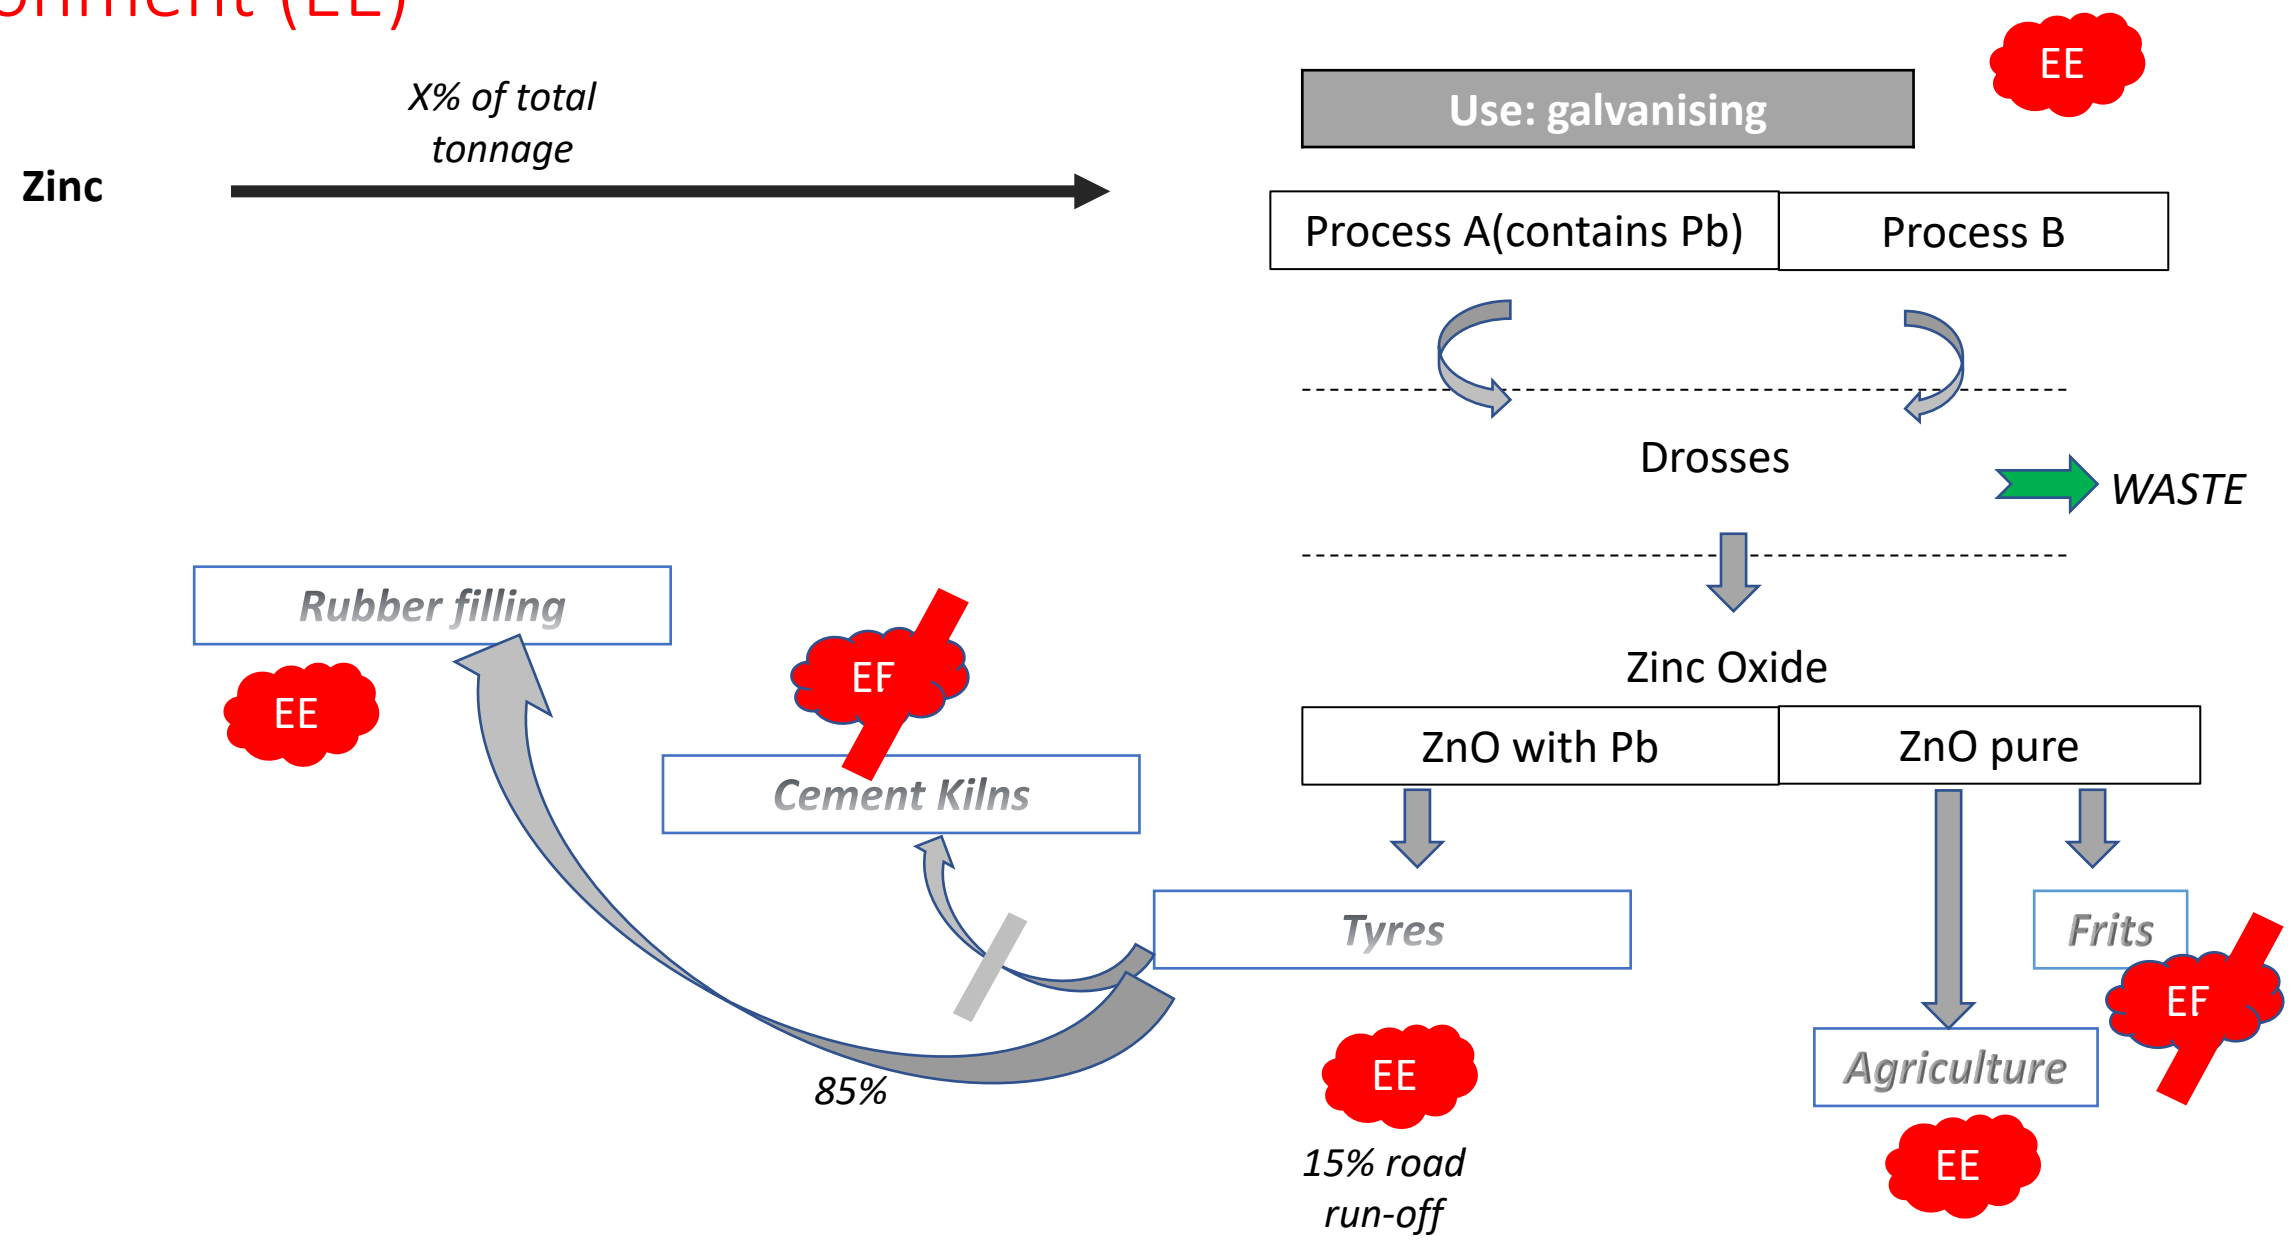

Notes: (1) Me refers to the metal substance analysed; (2) Me Compound stands for the Me compound analysed (e.g. Me oxide, Me chloride, Me sulfite); (3) smelter process is given as a typical example of metal production; (4) REACH registration dossiers that do not cover professional/consumer uses, typically report the uses advised against.

Example :substance zinc /uses: galvanisers

Example 1: substance zinc /uses: galvanisers + emissions  
environment (EE)

# Prioritisation for risk management

- Pb emissions to soil from ammunition > 70 % of total Pb emissions in the EU

## Total regional Pb emissions in the EU (info 2010)

# Prioritisation for risk management

- > 90 % of Ni emissions to soil from agriculture and
- > 2/3 of emissions to air from fossil fuel refineries and energy plants
- > 60% of emissions to water from households and SMEs

EU Ni emissions (in t) to:

Total Regional Ni emissions in the EU (info 2010)

# Key messages to conclude

Materials flow is very relevant for **metals and inorganics** because:

- those cannot be destroyed, hence “exposure based risk control” is a most effective risk management measure
- Those help identifying how much substance is in use in society and up for re-use, recycling or emissions

Materials Flow Mapping **helps to prioritise and define risk management effectiveness by:**

- Identifying where the main exposures may occur (i.e., areas for risk control)
- Identifying where materials are not recycled, so single use only (i.e., areas to consider alternative uses if possible)

# THANK YOU
